(54)Semi transparent tributary for synchronous transmission

An interface for converting a variety of incoming digital signals into SDH/SONET format for transmission on a synchronous digital network, by identifying the line code of the incoming digital signal, without identifying the information for OSI layer 2 or 3 processing, i.e. format of each packet. Headers are used to encapsulate incoming packets, and enable packets to be discriminated at the receiver. Advantages of performance monitoring capability and transparency are combined, Identifying line codes enables a greater degree of error detection, than a bit based interface. Also synchronisation can be simpler since line codes for padding can be added or deleted more easily than adding or subtracting bits. The interface is semi-transparent in the sense that identification of line codes limits the interface to those formats that use identifiable line codes, but without limiting to a particular OSI layer 2 or 3 frame format.

Description

RELATED APPLICATIONS

100011 This application relates to US patent application serial no 09/166,814 filed 6 October 1998 (Nortel Networks reference no ID1048) entitled CONCATEN-TION OF CONTAINERS IN SYNCHRONOUS DIGITAL HIERARCHY NETWORK, and to US patent application serial no 09/143,465 filed 27 August 1998 (Nortel Networks reference no ID0889) entitled PAYLOAD MAP-PING IN SYNCHRONOUS NETWORKS, US Patent Application 09/307812 (Solheim et al, entitled "Protocol Independent-Rate Device" filed on May 10 1999 and assigned to Nortel Networks Corporation) and US Patent Application serial no. 09/349087 (Roberts, entitled "MAPPING ARBITRARY SIGNALS INTO SONET", filed on 8 July 1999 and assigned to Nortel Networks Comoration, ref. 10420RO) all hereby incorporated by reference in their entirety.

FIELD OF THE INVENTION

[0002] The invention relates to interfaces for converting an incoming digital signal into a format for transmission on a synchronous digital network, to network elements comprising such interfaces, to corresponding receiver interfaces, to network elements having such interface, to corresponding methods and software, to
methods of using data transmission services to cause 30
data to be transmitted oversuch interfaces, and methods of detecting transmission errors using such interfac-

BACKGROUND TO THE INVENTION

[0003] It is known to provide boal area networks using protocols such as IEE 802.3, and ethernet (available in 10 megabilis per second, 100 megabilis per second and 1 gigabilis per second variations), and to couple local area networks together to create wide area networks (MAN). Wide area networks often use the public telecommunications network. Conversion is required from LAN protocols to conventional telecoms interfaces, for example E1, 83, T1 and STM-1. ESCON (Enterprise Systems Connection) and Fibrechamile are further examples of known LANs or Storage Area Networks, for connecting multiple storage devices.

[0004] It is also known to connect LAN's using optical transmission links, or optical transmission networks. There is a large installed base of SONET/SDH systems which can provide a transport service for ATM, SMDS, Frame Relay, T1, E1 and so on.

[0005] Mapping of one rate or format into another is well known. However, the standard or proprietary scheme allows transportation of a very specific set of signals, with format specific hardware. Generally separate hardware is required to map each type of signal on-

to SONET. It is known to map both continuous signals, which are synchronised to a lock, and burst format signals, which do not have a continuous clock. To transmit continuous signals, a wrapper is added to the continuous signal. However this produces formats which don't have a pre-defined fixed bit rate. The resulting signal cannot be time multiplexed to be transported on a high speed enlawn't, otherwise the phase or synchronicity of

the information is lost. [9006] I have also been proposed to transmit LAN signals such as ethernet signals directly over a DWDM (Dense Wavelength Division Multiploxing) link without using a synchronous protocol such as SORE/SSDH. This Implies one of the wavelengths is declicated to the LAN signal, as there is no way to multiplex other signals.

LAN signal, as there is no way to multiplex other signals onto the same wavelength. This may leave the great majority of the bandwidth of the given wavelength unused, which may be unsatisfactory in some circumstances.

stances

[0007] US Patent Application 09/30/7812 (Sohlemie et al, entitled "Protocol Independent-Rate Device" from May 10 1999 and assigned to Nortel Networks Corporation) discloses a method of transporting different pose of clients (IP, ATM, SONET, Ethernet ett) together. The Shandwidth assigned to amy given sub-rate channed can be provisioned without changing the hardware or software.

[0008] US Patent Application serial no. 09/349087 (Roberts, entitled "Mapping Arbitrary Signals Into SON-ET", filed on 8 July 1999 and assigned to Nortel Networks Corporation, ref. 10420RO), discloses mapping arbitrary signals into SONET to enable the signals to be recovered with low timing litter at low cost. A manner multiplexes numerous tributaries into the high rate SON-ET network. The mapper acts at the bit level to distribute stuffed bits uniformly interspersed across a frame, to enable an arbitrary input signal to be mapped onto the predefined fixed rate of the SONET/SDH output. This scheme and the above DWDM scheme both maintain inter frame information, and are both transparent to any frame format, meaning they are able to transport any frame format. However neither are frame aware and so have the disadvantage of not being able to carry out performance monitoring.

5 [0093] Other known schemes include encapsulation of frames for transmission, e.g. HDLC, (High-Level Data Link), published by Lucent on the IETF web pages. The SDL publication is approposal for encapsulating frames such as PP (Point to provide an interfame such as PP (Point to Potnocol) using SDL onto SONET/SDH. Such encapsulation schemes are frame aware and so can carry out performance monitoring. However, they have the disadvantages of not preserving information in the inter frame ages, and of the mapping being specific to the frame format, so the schemes are not transparent. [0010] it is also known to provide an interface he-

[0010] It is also known to provide an interface between an ethernet network and a SONET/SDH system at a router or a bridge. In this case, the router or bridge may have interfaces dedicated to more than one LAN protocol, and may multiplex data on to the SONET/SDH system, but this involves recognising the layer 23 protocol which defines the contents of each frame or pack-

[0011] A disadvantage of such devices is the complexity of processing the layer 2/3 information, and the buffering of packets intended for various destinations. Accordingly, such devices are dedicated, and cannot handle frames or packets of an arbitrary layer 2/3 protocol.

SUMMARY OF THE INVENTION

OSI layer 2 or 3 processing.

10012] It is an object of the invention to improve on 15 the known schemes. According to a first aspect of the invention there is provided a sending interface for convexting an incoming digital signal hies format for transmission on a synchronous digital network, the incoming digital signal having a group of bits coded by a prode-termined line code, the incoming digital signal sists ocarrying information for OSI layer 2 or 3 processing, the sending interface comprising:

circuitry for identifying the line code of the incoming digital signal, and circuitry for carrying out the conversion of the incoming digital signal according to the tine code identified, and independently of the information for

[0013] This is the first time the advantages of performance anobindizing capability, and transparency, have been, possible together, as will now be explained. An advantage of licenthying line codes is that it enables a greater degree of error detection and thus performance monitoring, compared to a bit based interface. This can be particularly significant if the interface is at a boundary between operating entities, such as a client/service provider boundary to a cost of control of the control of

[0014] Another advantage of the conversion being line odes aware, is that synchronisation can be simpler since fine codes for pacifing can be added or deleted more easily, using lower specification hardware, than is needed for adding or subtracting bits. The interface can be semi-transparent in the sense that identification of line codes limits the interface to those formats that use identifiable fine codes, but without limiting to a particular SSI layer 2 or 3 rame format.

[0015] Also, since OSI level 2 or 3 processing as carried out in a conventional router for example, is relatively complex, the interface of the invention can be greatly simplified and thus more easily integrated into other sequipment, compared to the router for example, an advantage of the use of a synchronous digital network is that it facilitates multiplexing, and other transmission

benefits.

Preferred features

- 5 [0016] Preferably the circuitry for identifying a line code comprises circuitry for identifying an idle code in the incoming digital signal. An advantage of this is that it enables the start and end of information streams such as variable length packets to be identified.
- Ø [0017] Preferably the circuitry for identifying a line code comprises circuitry for identifying a type of ide code, and the circuitry for carrying out the conversion is arranged to include in the synchronous data signal the type of idle code identified. An advantage is that inforsmother conversion arranged using different types of idle code will not be lost through the conversion.
- [0018] Proferably the incoming digital signal comprises a packets, and the circulary for carrying out the conversion is arranged to replace one or more of the idle codes of the head of the indicating the length of an associated one of the packets. This can enable a downstream receiver to identify the end of the associated packet, and thus identify tille codes, and maintain synchronicity with
- respect to packets and gaps between packets.

 [25] (2019) Preferably the header is of a fixed size. This can make synchronisation in the receiver easier.

 [26] Preferably the interface is arranged to adapt to
- receive incoming digital signals of more than one rate. An advantage is that the need for separate hardware of and software for each rate is no longer needed. The adaptation could be automatic or carried out under the control of a network management system.
- [0021] Preferably the format for the synchronous digtal network comprises SONET/SDH virtual containers. 35 [0022] Preferably the interface comprises cricultry for carrying out virtual concatenation of the SONET/SDH virtual containers. In this specification, the term "virtual concatenation" is used where the underlying network is unaware of any special relationship between the virtual or containers which make up a group of virtually concate
- containers which make up a group of virtually concalenated virtual containers. Particularly, although not exclusively, such frame based data may comprise OSI layer 2 data frames. An advantage is that delay variations between different paths in an SDH/SONET network can be handles.
- [0023] Preferably the interface comprises a multiplexer for multiplexing more than one incoming digital signal onto the synchronous digital signal. An advantage is that bandwidth can be used more efficiently.

Other Aspects of the Invention

[0024] According to another aspect of the invention there is provided an interface for converting an incoming figital signal into a format for transmission on a synchronous digital network, the incoming digital signal having a series of packets, and a group of bits coded by a predetermined idle code separating the packets, the inter-

face comprising:

circuitry for identifying the idle code of the incoming digital signal, and

circuitry for carrying out the conversion of the incoming digital signal according to the idle code identified.

[0025] According to a further aspect of the invention there is provided a receiver interface for recovering an 10 incoming digital signal that has been convented to a signal of a format for a synchronous digital network, the incoming digital signal having a group of bits coded by a predetermined (fine code, the incoming digital signal also carrying information for OSI layer 2 or 3 processing, 15 the receiving Interface comprising contracts.

circuitry for identifying linecode information in the formatted signal, and

circultry for replacing the Identified linecode information with corresponding linecodes independently of the information for OSI layer 2 or 3 processing.

[0026] An advantage is that this enables performance monitoring capability and transparency to be combined. 25 [0027] Prefeably the interface comprises a retimer, for inserting or deleting one or more of the linecodes to match the incoming data rate to the required outgoing data rate.

[0028] Preferably the receiver interface is arranged to receive SONET/SDH virtual containers.

[0029] Preferably the receiver interface comprises circultry for combining information from virtually concatenated containers before recovering the original incoming digital data signal.

[0030] Another aspect of the invention provides a corresponding method of, and corresponding software for converting an incoming digital signal into a synchronous digital signal.

[0031] Another aspect of the Invention provides an SDH/SONET network element comprising the above interface.

[0032] Another aspect of the invention provides a system comprising the above receiving interface and circuitry for monitoring QoS performance.

[0033] Another aspect of the invention provides a method of using a data transmission service provided over a telecommunication network, comprising the step of causing data to be transmitted across the above interface.

[0034] Any of the preferred features may be combined with any of the aspects set out above as would be apparent to a skilled person.

[0035] Other advantages will be apparent to a skilled person, particularly in relation to any further prior art other than that discussed above.

BRIEF DESCRIPTION OF THE DRAWINGS

[0036] Embodiments of the invention will now be described in more detail by way of example, with reference to the accompanying drawings, in which:

Figures 1 and 2 show typical telecommunications networks for data transmission which may make use of embodiments of the interface,

Figure 3 shows in schematic form, hardware elements of an embodiment of the interface,

Figure 4 shows functional elements of an embodiment of the interface, Figure 5 shows functional elements of an embodi-

ment of the receiver interface, Figure 6 shows in schematic form how an inter packet gap is replaced with header information in

an embodiment of the interface, and Figure 7 shows how the format of an incoming fibre channel frame is altered in the interface.

DETAILED DESCRIPTION

[0037] The embodiments described below have been conceived with a number of considerations in mind, including:

- To transport a number of different packet protocols between end users over a Sonet / SDH network.
 - To implement a tributary card (trib) for Sonet/SDH ADMs which can carry the widest possible range of packet protocols and data rates.
- To transport the packets as efficiently as possible in terms of required network bandwidth by using virtual concatenation if appropriate.

[0038] The examples described rely on the fact that a number of different packet protocols have a key feature in common. That is the transmission over a media of a constant bit stream with special codes used to indicate the gab between packets (and therefore the start and end of packets). Therefore if an interface such as a SonevSDH into can recognise the gap do der (usually called and of the constant packets) and therefore the start and end of packets). Therefore if an interface such as a SonevSDH into can recognise the gap do der user interface. In calso recognise complete packets on this interface. On recognition of a complete packet, the SonevSDH into can transfer the packet over the SonevSDH entwork to the ultimate designation. The packet must be transfer that packet over the SonevSDH into can transfer the sonevor the sonevor the sone sone can be considered to can be considere

rival rats.

(9039) On receipt of the packet at the destination SonevSDH rib (it is only necessary to avail the start of the
packet), the tick can deliver the packet to the end
packet), the tick can deliver the packet to the end
at a "nominal" rate. Some protocols use different tide
codes to transfer information. The type of tigle codes to transfer end across the SDH link and reproduced at
the destination.

at a rate equal to or higher than the maximum data ar-

Figs. 1 and 2. SONET/SDH Data Networks

[0040] Figs. 1 and 2 show in schematic form typical telecommunication networks for data transmission, in which embodiments of the interface may be used. The SONET/SDH format for a synchronous data network will now be described briefly.

[0041] Data transmission formats can be divided into synchronous or continuous formats such as SONETY SDH, and asynchronous or bural formats. Bural formats do not have a continuous dock, transmission of such signals do not require any given phase relationship between burals. On the other hand, the phase of the ofock of continuous formats has continuity under normal conditions, and the requency of the colock is bounded. Examples of such bounds are £20ppm (parts per million of the bit rate) and ±100 ppm.

[0042] The dominant signal format in fiber optic networks follows the synchronous standard SONET in North America and SDH elsewhere. In this specification, 2^a the term SONET/SDH will be used as a general tarm for both formats. SONET enables multiplexing, adding and dropping, and openeral transportation of signals. For a service, being able to be easily transported by a SONET metwork is a valuable attribute, in that it enables the network providers to make use of the large base of installed SONET-compatible equipment.

[0043] SONET is a physical carrier technology, which can provide a transport service for ATM, SMDS, frame relay, 71, E1, etc. As well, operation, administration, as maintenance and provisioning (CAMASP) features of SONET provide the ability to reduce the amount of back-to-back, multiplexing, and, more importantly, network providers can reduce the operation cost of the network.

10044] The SONET standards ANSIT110s and tebuore GR-255-CORE, define the physical interface, optical fine rates known as optical carrier (CC) signals, a trame format, and an OAMSP protocol, Optiolesisch and rame format, and an OAMSP protocol, Optiolesisch and conversion takes piece at the periphery of the SONET network, where the optical signals are converted into standard electrical format called the synchronous transport signal (STR), which is the optivalent of the option signal. Namely, the STS signals are carried by a respective optical carrier, which is defined according to the STS that it carries. Thus, an STS-192 signal is carried by an OC-192 optical storial.

[D045] The STS-1 frame consists of 90 columns by 9 rows of bytes, the frame length is 125 microseconds. A frame comprises a transport overhead (T041) occupying 3 columns by 9 rows of bytes, and a synchronous payload envelope (SPE) occupying 87 columns of 9 rows of bytes, The first column of the SPE is occupied by path overhead bytes.

[0046] As such, an STS-1 has a bit rate of 51.840 Mb/s. Lower rates are subsets of STS-1 and are known as virtual tributaries (VT), which may transport rates below DS3. Higher rates, STS-N, where N=1, 3, 12, ...192 or higher, are built by multiplexing tributaries of a lower

rate, using SONET add/drop multiplexers. An STS-N signal is obtained by interleaving N STS-1 signals STS-192 is made of 192 STS-1 tributaries, each separately visible, and separately aligned within the envelope. The individual tributaries could carry a different peshado, each with a different destination.

[0047] The STS-N has a TOH made of all N TOHs of the Individual tributaries, and a SPE made of all N SPEss of the Individual tributaries, each with its own POH. Some services, and the Individual tributaries, each with its own POH. Some services, and the Individual tributaries, and the Individual to STS-No signal (c for concatenation). The STS-1 is sind to STS-No signal (c for concatenation). The STS-1 is sind a STS-No signal is routed, multiblexed and transported as a longle entity rather than as N individual framported as a longle entity rather than as N individual of entitles. The TOH and the start of the SPE for the Noorattuens are agreerated by the same source, with the same clock. The first STS-1 in the concatenated signal carries the single set of POH, all that is required for an STS-No.

[0048] Magoling of one rate or format into another is

well known. Bellcore TR- 0253 describes in detail the standard mappings of the common asynchronous transmission formats (DSO, DS1, DS2, DS3, etc) into SON-ET. Similar mappings are defined for the ETSI hierarchy mapping into SDH. Optical transmission equipment has mapped one proprietary format into another. For example, FD-565 could carry Nortel's FD-135 proprietary format as well as the DS3 standard format. However, the standards or proprietary schemes allow transportation of a very specific set of signals, with format specific hardware. These methods of mapping cannot be used to map rates that vary significantly from the standard. Furthermore, these mappings are each precisely tuned for a particular format and a particular bit-rate, with e.g. a ±20ppm tolerance. If a signal has, for example, a bit rate even 1 % different than that of a DS3, cannot be transported within SONET. In addition, a different hardware unit is generally required to perform the mapping of each kind of signal. A line coding such as 8B/10B or 4B/5B may be used and produces a format with a higher rate than the original signal.

Figure 1

45 [0049] Figure 1 illustrates how an IESCON device 110 a fiberchannel device 100, and an ethernet LAM 120 may be coupled to other similar devices over a synchronous digital network such as an SONET/SDH network. The ESCON fiberchannel and ethernet devices are coupled to an SONET/SDH terminal multiplexer 130 which may be a 16Xo device as labelled. The ESCON fiberchannel and ethernet flow the trend processor of the tributaries. They may be in electrical or optical form. They are agregated in the terminal multiplexer using a sending instead of the terminal multiplexer using a sending instead of the terminal multiplexer using a sending instead to the terminal multiplexer using a sending instead of the terminal multiplexer using a more detail below. The SONET/SSH network includes intermediate elements 140 such as add-top multiplexers (ADM) or

cross-connects (one is shown labelled 64X).

[0050] A further terminal multiplexer 150 receives the SONET/SDH signal (which again may be either electrical or optical). The terminal multiplexer comprises a receiving interface 200 according to an ermbodiment of the invention, which can be used to de-multiplexe and recover enthe original ESOON and eithermet signals, them and forward them to respective destination ESOON, fiber-channel and eithernet devices 170, 160, 180. The transmission path may of course be bidirectional if there is a receiving and sending interface at both ends.

Figure 2

[0051] Figure 2 shows a similar network this time including both and SONET/SDH part and an optical part in the form of a ring. Three ADMs, 200,210,220 are shown on the ring. Where applicable, the same reference numerals have been used as in Figure 1. The fiberchannel devices have been omitted for the sake of clar- 20 ity. Various different architectures are conceivable for a SONET/SDH network. The optical ring may be WDM. In this case, a sending interface 190 according to an embodiment of the invention is provided in the 16Xe terminal multiplexer 130. The receiving interface 230 is provided partly at the ADM device 220 on the ontical ring. and partly at the junction of the SONET/SDH and the optical WDM parts. At the ADM 220 the tributaries are adapted and multiplexed into a virtual container format suitable for SONET/SDH, but are transmitted on one wavelength of the WDM network. At the junction with the SONET/SDH network, at a further ADM, 200 the virtual containers may be time division multiplexed with other virtual containers, and additional overhead added. Transmission can be carried out in both directions if a sending interface and a receiving interface are provided at each end.

Control of Rate

[0052] One implementation objective is for one Trib deployed by the network operator to be able to carry several end user data protocols. Using one physical interface, it is possible to exploit the fact that Fibrechannel, Escon and optical Gigabit Ethernet protocols all use the same line code and 'Idle/special' characters. Therefore one trib can handle these protocols using the same physical interface, if the trib can adapt to the specific data rate of the end user data. At the destination end. this data rate must also be known in order to output the data. The adaptation to the end user data rate could be automatic, with the actual data rate measured and communicated automatically to the far end, or it could be configured by a network management system. Configuration by a management system may be preferred, because it permits a network operator to charge for bandwidth usage. Each alternative of automatic adaptation or configuration could be implemented following well

known design principles, and so need not be described in more detail here. It is also possible to support multiple physical interfaces to additionally support other protocels such as Ethernet 100t7. Again the use of this physical interface by the end user could be automatically detected or configured. Again implementation of either could be carried out following well known design princicould be carried out following well known design princi-

ples, and so need not be described here in more detail.

Control of Idle Codes

19053 In order to cater for different protocols, it is necessary for the tible neither automateally detect the research (or the case) of the tible neither automateally detect more none in use, or to be configured. Once the protocol is nown, the various (lide codes and their meaning can be transcan be recognised at a receiver. The meaning can be transcered over the SDH link. An example of this is Fibrechannel which used 4 octet ordered sets, each of which begins with a "special character." This special character. This special character. This special character. This special character. The special character has performed to the serial link, they cannot be encoded in SDH octals.

[0054] An alternative would be for the tritle to 'spoof' (respond to) he various codes used between peacets. An advantage of spoofing is that I can reduce the delays caused by awaling confirmation form a destination during a thandshaking protocol. Such delays can significant in yeduce the data rate for long distance communicion (e.g. - 10km) for some protocols. For ESCON, spoofing is already an accepted technique, and it can be implemented in embodiments of the present invention, as desired.

[0055] A disadvantage of spoofing arises where the role of the semi-transparent trib is as an alternative to dark libre/ wavelength which would carry the interpackof et info. Responding would mean the trib takes on a role in the end users network which is outside the user's control and probably not what the user wants.

[0056] The data rate into an SOH trib at one end, and be the data rate out of an SOH this at the other, will not be collected. This means that from firms to time it will be necessary to prevent buffer underlycenflow at the destination. This will be achieved by stretching or shrinking the Inter-packet gap. For (Brochannel this stretch or shrink, will be in steps of 4 octats, (this is the behaviour referred 5 to by Fibrochannel as a "Relientina").

o by I-ordenanol as a N-demen; 00571 Preferably stratch/shrink only takes place during titles (and not during other special sequences), and only infrequently as determined by clock differences. Therefore the data transfer technique employed needs to preserve the original interpoket gaps as much as possible. Especially unpredictable expansion of the interpacket gap should be avoided because extra SDH bandwidth would be needed to cater for it. Preservation of inter-packet gaps requires that the packet delimination the sound of the sound of the sound to conjugate to conjugat

et gaps with the finest possible resolution.

Figure 3

f00581 Figure 3 shows in schematic form hardware features of an embodiment of the sending interface and the receiving interface, together on a single card. At the left hand side a back plane interface is shown carrying the SONET/SDH signals. Two separate paths are provided for redundancy, following well known protection path arrangements. An SDH framing device 300 is fed. by a multiplexer/de-multiplexer 310. This multiplexes or demultiplexes in the time domain a number of separate data paths, to couple the SDH framing device to virtual concatenation logic blocks 320.

[0059] Each virtual concatenation logic block is not essential, but if implemented, enables more efficient use of bandwidth, since a number of smaller virtual containers can be used in place of one large virtual container. Details of how to implement this virtual concatenation method are available in the above referenced US patent application entitled CONCATENTION OF CONTAIN-ERS IN SYNCHRONOUS DIGITAL HIERARCHY NET-WORK and have been made public to relevant standards bodies, and so are well known to those skilled in the art. so need not be described in more detail here. [0060] Each virtual concatenation block is coupled to a linecode recognition and mapping block 330. These blocks will be described in more detail below with reference to figures 4 and 5. In summary, they are for recognising the linecode of the incoming digital signal and performing an appropriate mapping ready for inserting the signal into the synchronous digital output signal. The line code of the incoming digital signal will be, recognised and used to determine start and end of frames. and therefore determine interframe information.

[0061] Other elements on the card include physical interfaces 340 for each of the line code recognition and mapping blocks, and a transport control subsystem 370. The framing block, the multiplexer, the virtual concatenation blocks, and the linecode recognition and mapping blocks can preferably be implemented in an ASIC or FPGA type device 360. Other parts may use more conventional commercially available hardware. A tynical arrangement of physical interfaces might include 2 ESCON, 2 Fiberchannel, and 4 ethernet(100baseT). with appropriate serial-parallel and parallel-serial convertors, and clock circuitry.

[0062] When operating as a receiving interface, as will be described with reference to figure 5 below, the signal flow is in the reverse direction. The recognition and mapping block must restore the original signal by recognising special headers, replacing them with the original inter frame information, and insert or delete unnecessary line codes to enable the signal to be output at the original rate independent of the precise rate of the synchronous digital signal.

Figure 4

[0063] Figure 4 shows functional elements in an embodiment of the Linecode recognition and mapping block 330 of Figure 3. It shows what happens to the data in one direction. The other direction is illustrated in Figure 5.

[0064] A physical interface 400,410,420 is adaptable

to different digital data signals, which may arrive on the same physical fiber or conductor. It may be made adaptable by carrying out multiple decode operations in parallel and selecting whichever works. It recovers clock, bit and byte/word alignment, it decodes the line code and may carry out serial to parallel conversion. The resulting outputs would include an 8 bit data bus plus an indication of normal or special character (KD), which will be explained in more detail below, and also indicates if it detects a linecode violation

100651 A selector 470 selects which physical interface or which type of decoded incoming data signal is to be fed to the next stage. A monitoring and control function 480 will take this information and recognise start of frame and end of frame, and count code violations, and numbers of good/bad frames for use by a performance

monitoring system.

[0066] The data including inter-packet data is sent to a FIFO (first in, first out) 490 for retiming. As illustrated. the FIFO bridges the domain of the data clock based on the incoming data signal, and the SDH container clock The output of the FIFO is fed to a register block which Is used to replace at least some of the inter packet information with header information. This encapsulation of the packets is done so as to enable packets to be detected at the receiver reliably, even if the packets are of variable length, without having to know the contents of the packet. This makes the transmission independent of the contents of the packet, and so independent of information for OSI layer 2 or 3 processing.

[0067] A block 500 is provided for FIFO control and for generating header information, special headers and normal headers for replacing line codes such as gap codes at appropriate times, depending on which type the input data signal is, and on which gap codes are present. Normal headers can't be created until a complete frame is in the FIFO. Special headers for stuffing into the SDH container are generated either while waiting for a complete frame in the FIFO or when the FIFO empties of ordered sets. To generate special headers to replace ordered sets requires examining sequences of ordered sets (eg sync clock request) and detection of a non-modulo 4 number of octets before a start of frame [0068] Note that a Normal header ones at the start of a packet and gives the distance to the next header which will be a special header at the end. Therefore the sending interface can't start sending a packet until the end is received in a FIFO. Therefore data over the SDH network can't run out during a packet. Therefore stuff special headers will only occur during intervals between

10

packets.

[0069] Block 520 is a selector to provide for insertion of headers, provide parallel-serial conversion and control output timing, ready for the next stage which would be multiploxing and SDH framing. Generation of the 5 SDH container's standard practice (may be one container, real concatenation or virtual concatenation.) and is equipment shoetiff.

Fig. 5, Receiving Interface functions

[0070] The receiving interface comprises a block 550 for maintaining synchronisation with the headers so that packet start and end points can be identified even for variable length packets. Any headers added purely for its stuffing, without carrying interpacket information are discarded here. An alarm may be raised if header sync is lost, since this may cause loss of data if the packet start and end points cannot be recognised. Sarial-pariallel conversion would be carried out on the data. A small FIFO 560 is provided at the next stage, controlled by a FIFO III monitor 550, to bridge the two clock domains, the SDH container clock and the output data clock domain. The FIFO size hould be enough to overcome SDH overhead gaps, discard of stuff headers and allow for data rate differences.

10071]. A register blook 570 is provided under the control of block 850 to enable replacement of headers with corresponding ordered sets, to achieve recovery of the original signal. Furthermore, special processing of 30 Fiberchannel SOF and EoF is carried out here, as will be described with reference to figure 7. Selector block 950 is also controlled by block 580 and enables insertion of headers at the correct time. This block outputs an 8 bit signal with an indication of normal or special charactures. John 100 pt. 100 p

[0072] A performance monitoring block 590 may be provided here or remotely, for establishing performance for use in QoS measurements which may be used as a basis for charging a client by a service provider, for data transmission.

The Clocks at the receiving Interface

[0073] On receipt of data from the SDH link, special headers used for stuffing on the link are discarded. Other special headers are converted to the appropriate ordered sets.

[0074] Once this is done, the data rate is the same as the end user input data rate at the other end of the link, so two alternatives are available to derive a clock for outputting the data:

a)Use a PLL locked to the data: This has the advantage of a matching data rate, but has disadvantages of jitter, smoothing circuitry and so on. b)Synthesize nominal data clock frequency.

This has the advantage of generating a clearer clock but requires data rate matching by, inserting / delating link follow between packets. Life insertion is relatively easy to implement (but must not occur in the middle of a sequence of ordered sets), in any case, inserting or deleting idle codes is considerably assier than inserting or deleting bits a high data rates. Life deletion may require a wait of a couple of frames for an opportunity.

100751 A preferred implementation involves using an SOH node clock (4+ 45.ppm to generate a data clock at upper end of allowed tolerance. This would give a greater likelihood of having to insert than delete ide oodes. Clock tolerance is 4+ 100ppm for Fiberchannel. Ethemer / Fast Ethemet is 4+ 50 ppm (RMII consortium spec) (FMII consortium spec includes some useful notes on allowed shrinklage of interpacket gaps. The Gigabit Ethemer spec is 4+100 ppm. It's been suggested that devices should tolerate about 4+150 ppm to accept data from any NICs.

Fig. 6 Packet delineation in the receiver:

[0076] To detect packet start and end at the receiver, the well known HEC (Header Error Correction) sech-inque used and standardised for ATM cannot be used if the delineation has to cope with unknown and varying packet lengths. Therefore, it is modified as shown in figure 6.

§ 0077] The delineation now uses a four octet sequence in which the two octs tength felid replace the knowledge of the fixed length ATM cells, the other two octets are the CRC-16 of the length. The length cates the distance in tytes to the next "neader," This occupies with the complete the distance in tytes to the next "header," This in errors induced in the length field, but there are known exchallenge the characteristic and the complete t

[0079] It can be seen that a 4 octet header quantises the users inter-packet gap in steps of 4 octets, respect to channel minimum interpacket gap is 9 Primitives tros of the state of the

5 [0079] A current assumption for Fibrechannel is that at the receiving interface the normal header (indicates start and length of a packet) can always be replaced by the ordered set meaning Idle. If this assumption isn't always valid, it may be necessary to introduce extra code options into the special headers, so that the preceding special header also indicates the ordered set of the next one. For Gigabit ethernet it is replaced by the SofF special character and three octets of organible.

[0080] There should be at least two headers between fremes (the tris hould probably be able to operate with equipment which has already shrunk the interpacket gap somewhat). This could be used to improve the reliability of acquiring sync to the headers. The carriage of interpacket gap information could be exploited to make a VMN with the equivalent of Ethernet autonogoliation.

Special Headers

[0081] To distinguish the Special header from the Normal header, one way is to reduce the maximum possible packet length.

[0082] Lots of ways to do this, easiest to explain is the reduce it from 2"16 to 2"16 4. Any length values in the range 2"16-X to 2"16 mean this is a special header (of length 4 octals) which will be followed by a normal header.X codes are therefore now available to encode the meaning of the primitive (4 octals) which this header replaces.

[0083] One code is reserved for a header used solely for stuffing the data fail to suit the SDH data rate. It is notly inserted (as are all headers) between packets, and it is discarded at the other and of the SDH link. For use with protocols (ag ethernet) in which the interpacket gap 30 is not quantised in units of 4 cotats, there should be enough codes to include the information that this header replaces alther 5.5, 6 or 7 cotets of interpacket gap code

100841 Not many codes are needed for the information 33 which may be in the idle codes, at least for the incoming digital data formats described above. Fibre channel has about 9 'Primitives' including those used for Idle and for Clock Synchronisation, All are 4 octets. For Ethernet there are 4 length options each of which needs to also 40 represent the underlying link code. The number of link codes for Gigabit Ethernet seems to be 2 (4 octet) for configuration, effectively 1 for idle (2 octets), and 2 or 3 for the End of Frame to denote ending with idle or carrier extend. Even code group boundaries may need to be treated differently. The error propagation special character should not be created by Gigabit ethernet devices other than repeaters, so it's assumed that the trib will not receive any. It may be desirable to create some in the link, following detection of input code violations.

Fig 7,Special case of delineation of Fibrechannel frame

[0085] The fibre channel Start of Frame and End of Frame indications are also ordered sets which once decoded from 8b/10b cannot be sent directly over an octet structured link. There are several possible SOF and

EOF delimiters with different meanings.

One way to handle this is to specify as follows:

[0086] The first 4 octets following a Normal header en-

code the type of SOF The last 4 coetes in a packet (pefore any type of Header) encode the type of EOF. [0087] The 'knowledge' that the link is Forechannel could be provisioned or it could be automatic (rwoving recognition of user data rate/ordered sets, and encoding ordered sets into special headers so that the far end also knows). It would be possible to encode more directly

- ordered sets into special headers so that the far end also homes). It would be possible to encode more directly the ordered sets (as opposed to 'code' y - fibrechannel SOF normal class 2) The running disparity used but 100 bit normally based on the current running disparity on a character by character basis. But for ordered sets, 5 its defined to reach character. So it's probably safer to stay with a 'code book' of ordered sets (which might need to be upgraded in future).
- [0088] To delineate Gigabit ethernet frames: There is a single special character used for Solf* (12.77) as a single special character used for Solf* (12.77) of specials the first pre-amble cotet. So a normal header will replace the Solf* and the following there presented cotets. A single special character is used for Eoff* who follows the last cotet of data, but this seems to be cloud with the sems to decide the solf of the special character and then a "either further centrer extends or clides. The first scallable header following a frame needs to encode this difference."

Handling code violations

[0089] Fibrechannel permits modifying the EOF ordered set to indicate a frame with code vlolations. Possibly the more transparent sculption is to carry to the destination and the information that a code violation occurred and their get me desination to create another code violation at about the right place.

Scrambling:

40 [0090] Scrambling may be useful to prevent 'killer packets' from either disturbing Std sync recovery possibly) disturbing header sync. Options available include: selfsync over packet contents or whole payload (if over packet contents or whole payload (if over packet contents to the next), or self-reset type. If self-reset type, which would restant at the beginning of each packet, the usual security objections can be overcome by using random seed values. The seed value could be transferred by waiting for a long run of kiles between packets and then using a special header.

Notes on other matters:

[0091] Normal headers can't carry any info other than length, so the far end needs to know (from previous special headers) that the link is Ethernet. There are two options for the location of the normal header with Sigabit Ethernet. It could be located starting with the /S/ start of packet indicator on the "enert, or it could be aligned starting 4 octets before as proposed for fibrechannel. If 4 octets before, then the first 4 octets of the packet would be ore-amble or a code to indicate pre-amble.

[0092] Gigabit ethemet carrier extend is only used on half-dulpbx links, which would be illogical (very slow) over a Wan. Hence ignore packets ending with carrier extend, otherwise a code is needed for a special header to indicate Eoff with carrier extend and a code to indicate large and indicated indicat

Other Examples, Variations

[0093] Although the embodiments described show replacing idle codes with headers to maintain the bit rate, it would be possible to simply add headers without replacing idle codes. This would result in the bit rate changing for transmission.

[0094] The packet delineation could be performed use ing SDL encapsulation techniques as an alternative to the packet delineation described above using the normaterial statement of the codes by special harders and the insertion or deletion of idle codes to compensate for clock differences, could be combined with such SDL- type encapsulation.

[0095] Above has been described an interface for converting a variety of incoming digital signals into SDH/ SONET format for transmission on a synchronous digital network, by identifying the line code of the incoming 30 digital signal, without identifying the information for OSI layer 2 or 3 processing, i.e. format of each packet. Headers are used to encapsulate incoming packets, and enable packets to be discriminated at the receiver. Advantages of performance monitoring capability and trans- 35 parency are combined. Identifying line codes enables a greater degree of error detection, than a bit based interface. Also synchronisation can be simpler since line codes for padding can be added or deleted more easily than adding or subtracting bits. The interface is semitransparent in the sense that identification of line codes limits the interface to those formats that use identifiable line codes, but without limiting to a particular OSI laver 2 or 3 frame format.

[0096] Other variations of the described embodiments, and other applications of the invention can be conceived and are intended to be within the scope of the claims. References to software are intended to encompass both software on a computer reachable medium, and software delivered over a transmission medium.

Claims

 A sending interface for converting an incoming digital signal into a format for transmission on a synchronous digital network, the incoming digital signal having a group of bits coded by a predetermined line code, the incoming digital signal also carrying information for OSI layer 2 or 3 processing, the sending interface comprising:

- circuitry for identifying the line code of the incoming digital signal, and
- circuitry for carrying out the conversion of the incoming digital signal to the line code identified, and independently of the information for OSI layer 2 or 3 processing.
- The sending interface of claim1, the circuitry for Identifying a line code comprising circuitry for identifying an idle code in the incoming digital signal.
- The sending interface of claim 1, the circultry for identifying a line code comprising circultry for dientifying a type of (file code), and the circultry for carrying out the conversion being arranged to include in the synchronous data signal the type of idle code identified.
- 4. The sending interface of any of claims 1 to 3, where in the incoming digital signal comprises packets, and the disculty for carrying out the conversion its arranged to replace one or more of the idle codes with a header for indicating the length of an associated one of the packets.
- The sending interface of claim 4, wherein the header is of a fixed size.
- The sending interface of any of claims 1 to 5, wherein the interface is adaptable to receive incoming digital signals of more than one rate.
- The sending interface of any of claims 1 to 6, wherein the format for the synchronous digital network comprises SONET/SDH virtual containers.
- The sending interface of claim 7, the interface comprising circuitry for carrying out virtual concatenation of the SONET/SDH virtual containers.
- The sending interface of any of claims 1 to 8, the interface comprising a multiplexer for multiplexing more than one incoming digital signal onto the synchronous digital signal.
 - 10. A sending interface for converting an incoming digital signal into a format for transmission on a synchronous digital network, the incoming digital signal having a series of packets, and a group of bits coded by a predetermined tide code separating the packets, the sending interface comprising:

circuitry for identifying the idle code of the in-

s

25

coming digital signal, and circuitry for carrying out the conversion of the incoming digital signal according to the idle code identified.

11. A roseliver interface for recovering an incoming digital signal from a signal of a format used for transmission over a synchronous digital network, the incoming digital signal having a group of bits coded by a predetermined line code, the incoming digital of signal also carrying information for OSI layer 2 or 3 processing, the receiving interface comprehen:

circuitry for Identifying line code information in the formatted signal, and

circultry for replacing the identified line code information with corresponding line codes independently of the information for OSI layer 2 or 3 processing.

- 12. The receiver interface of claim 11, further comprising a retimer, for inserting or deleting one or more of the line codes to match the incoming data rate to a required outgoing data rate.
- The receiver interface of claim 11 or 12 arranged to receive SONET/SDH virtual containers.
- 14. The receiver interface of any of claims 11 to 13 further comprising circultry for combining information from virtually concatenated containers before recovering the original incoming digital data signal.

15. A method converting an incoming digital signal into a format for transmission or a synthemosur-digital—3 network, the incoming digital signal having a group of bits coded by a pradetermined line code, the incoming digital signal also carrying information for OSI layer 2 or 3 processing, the method comprising the steps or 1.

identifying the line code of the incoming digital signal, and converting the incoming digital signal according to the line code identified, and independently of the information for OSI layer 2 or 3 processing.

- Software for carrying out the method of claim 15.
- 17. A SDH/SONET notwork element comprising a sending interface for converting an incoming digital so signal into a format for transmission on an SDH/ SONET network, the incoming digital signal having a group of bits coded by a predetermined line code, the incoming digital signal also carrying information for GSI layer 2 or 3 processing, the sending interface comprising:

circuitry for identifying the line code of the in-

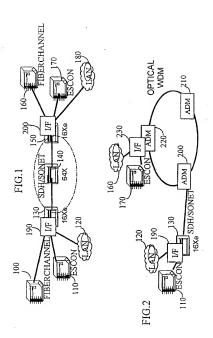

coming digital signal, and circuitry for carrying out the

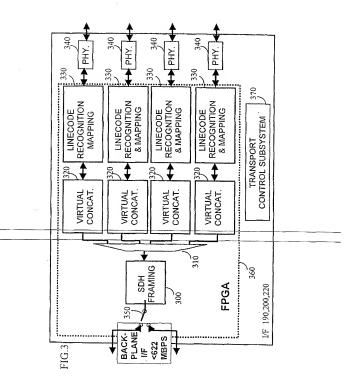

circuitry for carrying out the conversion of the incoming digital signal according to the line code identified, and independently of the information for OSI layer 2 or 3 processing.

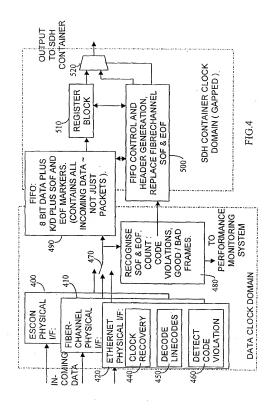

18. Apparatus for detecting transmission errors by a synchronous digital network used to transmit an incoming digital signal, the apparatus comprising a receiver interface for recovering the incoming digital signal from a signal of a format used for transmission over the synchronous digital network, the incoming digital signal having a group of bits coded by a predetermined fine code, the incoming digital signal also carrying information for OSI layer 2 or 3 processing, the receiving interface comprising.

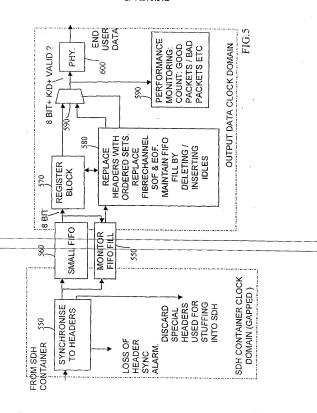

> circuitry for identifying line code information in the formatted signal.

- circuitry for replacing the identified line code information with corresponding line codes independently of the Information for OSI layer 2 or 3 processing, and
- circuitry for determining errors in the recovered signal compared to the incoming digital signal, independently of the information for OSI layer 2 or 3 processing.
- 19. A method of using a data transmission service provided over a telecommunication network, comprising the step of causing data to be transmitted across a sending interface as set out in claim 1.
